ABSTRACT - Gamma neurons [1] are employed in this paper to construct a feed-forward multi-layer network to perform automatic speech recognition. Gamma network can approximate complex time-dependent connection weights with simple network structure. Its structure parameters can be learned in the training phase to determine an optimal structure for dynamics processing to fit the particular application task. An error back-propagation like learning algorithm is derived and experimental results of speaker-independent phoneme recognition are discussed.

1. INTRODUCTION

One of the main problems in applying neural network models to automatic speech recognition is how to process time-varying information in speech signals in an effective way. A possible solution to this problem is to introduce time-delay mechanism for neuron inputs. In this way, the neuron output depends not only on the current input but also on the time-varying feature of the input signal in the past. In general, the system equation for this kind of time-delay neurons can be formulated by the following convolution model:

\[ y(t) = \mathcal{F} \left( \vec{w}_0 \vec{x}(t) + \int_0^t \vec{w}(t-s) \vec{x}(s) ds + \eta \right) \] (1)

Here \( y(t) \) is the neuron output, \( \vec{x}(t) \) is a vector of inputs, \( \vec{w}_0 \) is a vector of connection weights for the current input, \( \vec{w}(t) \) is a vector of time-dependent connection weights for input signals in the past, \( \eta \) is the threshold value, \( \mathcal{F}(\cdot) \) is a monotonically increasing non-negative function and the superscript \( ^t \) denotes vector transposition.

Due to the complexity of the general convolution model, \( \vec{w}(t) \) must be simplified in order to construct a network in practice. A common technique is to decompose \( \vec{w}(t) \) into a weighted sum of some basis functions, that is

\[ \vec{w}(t) = \sum_{\tau=1}^{\tau} \vec{w}_\tau g_\tau(t) \] (2)

Several research have been carried out along this direction. Waibel et al has proposed time-delayed neural network (TDNN) [2] by employing impulse functions as the basis functions:

\[ g_\tau(t) = \delta(t - d_\tau) \] (3)

In concentration-in-time neural network (CITN network) of Tank et al [3], the integrands of the \( \Gamma \) functions are proposed to serve as the basis functions, i.e.,

\[ g_\tau(t) = \left( \frac{t}{d_\tau} \right)^\tau \exp \left( \tau \left(1 - \frac{t}{d_\tau} \right) \right) \] (4)

Gaus functions are chosen as the bases in the TEMP2 neural network proposed by Bodenhausen et al [4]

\[ g_\tau(t) = \frac{1}{\sqrt{2\pi}\sigma_\tau} \exp \left( -\frac{(t - d_\tau)^2}{2\sigma_\tau^2} \right) \] (5)
Recently De Vries et al [1] suggests Gamma neuron to process temporal patterns which uses Gamma functions as the bases in decomposing \( \tilde{w}(t) \),

\[
g_{\tau}(t) = \frac{\mu^{\tau}}{(\tau - 1)!} t^{\tau-1} \exp(-\mu t) \tag{6}
\]

TDNN is quite successful in recognizing English phonemes [2]. However, it is obvious from Eq. (2) and (3) that one cannot achieve good approximation by employing impulse functions as basis functions. The TDNN structure specifies a fixed delay range to process the dynamic feature of the input signal. However, there is no theoretical ground to determine the maximum delay \( T \). The strength of a CIN network is limited by its simple network structure. Only the input layer of a CIN network employs time-delay neurons, and there is no hidden layer in the network. Besides, no comprehensive learning procedure is proposed for a CIN network. The principal advantage of the TEMP2 network is that the structure parameters of the network (i.e., delay time \( \sigma_{\tau} \) and delay window width \( \sigma_{\tau} \) in the Gauss function) are adaptive and can be learned from the training data. However, the relatively heavy computation requirement in a TEMP2 network usually results in the fact that only a few basis functions are employed in Eq. (2) which certainly degrades the approximation capability of the network. Besides, there is no easy implementation of the TEMP2 network using delay operators.

On the other hand, a Gamma neuron can take advantage of the nice properties of Gamma functions to realize the required computation in a very effective way. Moreover it is shown that any time-dependent function \( \tilde{w}(t) \) can be well approximated for a sufficiently large \( T \) using Eq. (2) and (6) if \( \tilde{w}(t) \) exponentially decays to zero as \( t \) approximates to infinity [5]. In addition, static neuron model, TDNN and CIN can all be seen as special cases of a Gamma neuron [1]. So Gamma neurons are very attractive as elements of a neural network which is capable of processing time-varying information of complex input patterns such as speech signals.

A multi-layer network structure with Gamma neurons in both its input layer and hidden layers (called Gamma network hereafter) are proposed and tested in an automatic speech recognition experiment in this paper. Section 2 summaries the implementation of a Gamma neuron originally proposed by De Vries et al [1]. Section 3 discusses the training method for a multi-layer Gamma network. An error back-propagation algorithm is proposed to learn the connection weights of a Gamma network \( \tilde{w}_0, \tilde{w}_1, \ldots, \tilde{w}_T \) as well as the network structure parameter \( \mu \)'s. With such an algorithm, a Gamma network can automatically determine its delay structure and adjust the dynamics processing capability for each Gamma neuron in the network from a given set of training data to achieve an optimal performance. Finally, experimental results of recognizing speaker-independent phonemes (/b/,/d/,/g/) by means of a Gamma network are presented in Section 4.

2. THE STRUCTURE OF MULTI-LAYER GAMMA NETWORK

Defining Gamma state variables \( \tilde{x}_{\tau}(t) \) as

\[
\tilde{x}_0(t) = \tilde{x}(t) \tag{7}
\]

\[
\tilde{x}_\tau(t) = \int_0^t g_{\tau}(t-s) \tilde{x}(s) ds \quad \tau \geq 1 \tag{8}
\]

and substituting Eq. (2), (7), (8) into (1), one gets the simplified system equation for a Gamma neuron:

\[
y(t) = \mathcal{F} \left( \sum_{\tau=0}^{T} \tilde{w}_{\tau} \tilde{x}_{\tau}(t) + \eta \right) \tag{9}
\]

Using the derivative property of Gamma functions in Eq. (6), it is easy to show that the
derivatives of the Gamma state variables $\tilde{z}_r(t)$ should follow:

$$\frac{\partial \tilde{z}_r(t)}{\partial t} = -\mu \tilde{z}_r(t) + \mu \tilde{z}_{r-1}(t) \quad \tau \geq 1$$  \hspace{1cm} (10)

Under the assumption that the sampling frequency, $f_s$ (corresponding to the frame rate of a speech recognition system), of the acoustic features, $\tilde{z}(t)$, of the input signal is higher than the Nyquist frequency, the discrete system equation of a Gamma neuron is

$$\tilde{z}_0(n) = \tilde{z}(n) \quad (1)$$

$$\tilde{z}_r(n) = (1 - \mu)\tilde{z}_r(n-1) + \mu \tilde{z}_{r-1}(n-1) \quad \tau \geq 1 \quad (2)$$

$$y(n) = \mathcal{F} \left( \sum_{\tau=1}^{T} w_{\tau} \tilde{z}_r(n) + \eta \right) \quad (3)$$

The above operation can be effectively realized by a Gamma node as illustrated in Fig. 1 (D denotes a delay operator in the figure).

![Gamma neuron diagram](image)

**Figure 1.** The Structure of a Gamma neuron

The recursive memory structure in Eq. (12) is stable for $0 \leq \mu \leq 2$ and the interesting memory structure is obtained for only $0 \leq \mu \leq 1$ [1]. For $\mu = 0$, a Gamma neuron is reduced to a normal static neuron. A Gamma neuron works as a discrete time CITN if $0 < \mu < 1$. It becomes a TDNN when $\mu$ is set to 1. The strength of the Gamma neuron is the structure parameter $\mu$ can be learned in the training phase, so, the optimal temporal structure is determined to fit the problem to be solved.

Multi-layer Gamma network is purely a feed-forward network. Every processing units in its every layer is a Gamma neuron. The output of each Gamma neuron is the input of all the Gamma neurons in its next succeeding layer. Assuming $K$ layers in a Gamma network (including the input layer) with $M^k$ Gamma neurons in the $k^{th}$ layer, one can represent the system equation of the Gamma network as

$$y^k_i(n) = \mathcal{F} \left( \sum_{i=1}^{M^{k-1}} \sum_{\tau=1}^{T} w_{ji,\tau} x^k_j(n) + \eta^k_j \right) \quad k = 1, 2, \ldots, K \quad (4)$$

$$x^k_{ji,\tau}(n) = (1 - \mu^k_j) x^k_{ji,\tau}(n-1) + \mu^k_j x^k_{ji,\tau-1}(n-1) \quad (5)$$

$$x^k_{ji,0}(n) = y^{k-1}_i(n) \quad i = 1, 2, \ldots, M^{k-1} \quad (6)$$

Here $y^k_i(n)$ and $x^k_{ji,\tau}(n)$ are the output value and the value of the $i^{th}$ component of the $\tau^{th}$ Gamma state variable, respectively, of the $j^{th}$ Gamma neuron in the $k^{th}$ layer at time $n$. $w_{ji,\tau}$
is the connection weight between the output and the $i^{\text{th}}$ component of the $\tau^{\text{th}}$ Gamma state variable of the $j^{\text{th}}$ Gamma neuron in the $k^{\text{th}}$ layer. $\mu_{j}^{k}$ is the structure parameter for the $i^{\text{th}}$ input component of $j^{\text{th}}$ Gamma neuron in the $k^{\text{th}}$ layer, $\eta_{j}^{k}$ is the threshold value of $j^{\text{th}}$ Gamma neuron in the $k^{\text{th}}$ layer. $y_{j}^{k}(n) = x_{j}(n)$ is the input value in the $j^{\text{th}}$ input node of the network at time $n$.

In Eq. (14), all Gamma neurons in the network have the same number of Gamma state variables, i.e., the parameter $T$ is common to all the Gamma neurons. Since every Gamma neuron has its individual structure parameter $\mu_{j}^{k}$ for every input component of it, the capability of processing time-varying information for each input component in every Gamma neuron is different. In this manner, the network is highly powerful to process complex dynamic information.

Moreover, since the structure parameters $\mu_{j}^{k}$'s are learned from the training data, the network structure is adaptive to the particular application task.

3. TRAINING A MULTI-LAYER GAMMA NETWORK

It is quite straightforward to generalize the error back-propagation algorithm [6] of Rumelhart et al. to train a Gamma network. Let $\mathbf{x}(0), \mathbf{x}(1), \ldots, \mathbf{x}(N)$ be a training sequence and $\mathbf{d}(0), \mathbf{d}(1), \ldots, \mathbf{d}(N)$ be the corresponding desired network output ($\mathbf{x}(n)$ and $\mathbf{d}(n)$ are $M^{N}$-dimensional and $M^{K}$-dimensional vectors, respectively). The network parameter set $\Theta = \{\mathbf{\mu}_{i}^{j}, \mathbf{\eta}_{i}^{j}\}$ can be obtained through the following stochastic optimization process:

$$
\Theta^{*} = \min_{\Theta} E = \min_{\Theta} \frac{1}{2} \sum_{n=0}^{N} \sum_{j=1}^{M^{K}} (y_{j}^{K}(n) - d_{j}(n))^{2}
$$

(17)

$s_{j}^{k}(n)$ and $\delta_{j}^{k}(n)$ are defined as the net input and error variable for the $j^{\text{th}}$ Gamma neuron in the $k^{\text{th}}$ layer at time $n$, i.e.,

$$
\sigma_{j}^{k}(n) = \sum_{i=1}^{M^{k+1}} \sum_{\tau=0}^{\tau} w_{ji}^{k} \sigma_{ji}^{k}(n) + \eta_{j}^{k}
$$

(18)

$$
\delta_{j}^{k}(n) = \frac{\partial E(n)}{\partial \sigma_{j}^{k}(n)} = \frac{\partial E(n)}{\partial y_{j}^{k}(n)} \cdot \frac{\partial y_{j}^{k}(n)}{\partial \sigma_{j}^{k}(n)} = \mathcal{F}'(\sigma_{j}^{k}(n)) \cdot \frac{\partial E(n)}{\partial y_{j}^{k}(n)}
$$

(19)

where

$$
E(n) = \frac{1}{2} \sum_{j=1}^{M^{K}} (y_{j}^{K}(n) - d_{j}(n))^{2}
$$

(20)

is the network output error at time $n$. The following recursive formula for computing $\delta_{j}^{k}(n)$ can be derived if a sigmoid function is employed for $\mathcal{F}(\cdot)$:

$$
\delta_{j}^{K}(n) = y_{j}^{K}(n) \cdot (1 - y_{j}^{K}(n)) \cdot (y_{j}^{K}(n) - d_{j}(n))
$$

(21)

$$
\delta_{j}^{k}(n) = \mathcal{F}'(\sigma_{j}^{k}(n)) \sum_{j=1}^{M^{k+1}} \delta_{j}^{k+1}(n) \cdot \sum_{\tau=0}^{\tau} w_{ji}^{k+1} j_{jir}^{k+1}(n)
$$

(22)

where $j_{jir}^{k+1}(n) = \frac{\partial x_{jir}^{k+1}(n)}{\partial y_{f}^{k}(n)}$ can be recursively computed from Eq. (7) and (8) by

$$
J_{j0}^{j}(n) = 1
$$

(23)

$$
J_{ji}^{j}(n) = J_{ji}^{j},_{-1}(n) - J_{ji}^{j},_{-1}(n)
$$

(24)

$$
J_{j0}^{j}(n) = \exp(-\mu_{j}^{k} n_{j0}^{k})
$$

(25)

$$
J_{ji}^{j}(n) = \frac{\mu_{j}^{k}}{\tau} \cdot n_{j0}^{k} \cdot J_{ji},_{-1}(n)
$$

(26)

143
Using the following derivatives, the network parameters can be determined by the well-known steepest descent searching method or any other optimization procedure:

\[
\frac{\partial E}{\partial \eta_{ij}^k} = \sum_{n=0}^{N} \delta_{ji}^k(n) \tag{27}
\]

\[
\frac{\partial E}{\partial w_{ji}^k} = \sum_{n=0}^{N} \delta_{ji}^k(n) z_{ji}^k(n) \tag{28}
\]

\[
\frac{\partial E}{\partial \mu_{ji}^k} = \frac{1}{\mu_{ji}^k} \sum_{n=0}^{N} \delta_{ji}^k(n) - \sum_{\tau=1}^{T} z_{ji}^k(n) - z_{ji,r+1}(n) \tag{29}
\]

4. PHONEME RECOGNITION EXPERIMENTS

English phoneme recognition experiments with a subset of the DARPA TIMIT speech database [7] are performed to evaluate the performance of a Gamma network trained by the proposed learning algorithm. Three consonants (/b/, /d/, /g/) in different phonetic contexts are extracted for recognition from continuously spoken sentences according to the phoneme boundaries provided by the database. Since these three consonants are very short in duration and their characteristics are also reflected in the surrounding phonemes, a 16ms segment of signals is included both before the onset and after the offset of these consonants.

The speech material was spoken by 630 speakers, each spoke five randomly selected sentences from the MIT acoustic-phonetic corpus (there are in total 450 sentences in the corpus). 3146 tokens of three consonants from 420 speakers are employed as the training set and 1209 tokens from the rest of speakers are served as the testing set. Table 1 shows the number of training and testing tokens for each consonant.

The speech signal is sampled at 16KHz. After Hamming windowing, a 256-point discrete Fourier transformation is applied every 4ms. The acoustic features employed in the experiment are 16 mel-scaled cepstrum coefficients [8] computed from the logarithm output of a bank of 20 critical bandpass filters [9].

A Gamma network with one hidden layer is employed in the experiment. The network consists of 16 Gamma units in the input layer, 20 Gamma units in the hidden layer and 3 units in the output layer. Each unit in the input layer receives a mel-scaled cepstrum coefficient each 4ms. Every output unit corresponds to one consonant class. Gamma units in the input layer have 4 Gamma state variables and those in the hidden layer have 6 Gamma state variables. All network parameters are initialized with random values. After the training process terminated, a correct recognition rate of 82.4% is obtained for the testing consonants.

For the purpose of comparison, a TDNN with the similar architecture, i.e., 16, 20 and 3 units in the input, hidden and output layers, 4 and 6 delay operators for units in the input and hidden layers respectively, is constructed and trained by the standard error back-propagation algorithm. When tested with consonants in the testing set, a correct recognition rate of 78.6% is obtained.
Table 2 shows the confusion matrices for both the Gamma network and the TDNN.

5. CONCLUSIONS

This paper presents a Gamma neural network architecture for recognition of patterns with temporal structures. A learning algorithm based on the principle of error back-propagation is derived. Speaker-independent English phoneme recognition experiments are performed to verify the proposed network architecture and the associated learning algorithm. An improved recognition performance is observed when a Gamma network is compared with a TDNN.
